# Lecture 7 – First-Class Functions

COSE212: Programming Languages

Jihyeok Park

2023 Fall

#### Recall

- F1VAE VAE with first-order functions
  - Concrete and Abstract Syntax
  - Evaluation with Function Environments
  - Interpreters and Natural Semantics
  - Static Scoping vs Dynamic Scoping

- In this lecture, we will learn **first-class functions**.
- FVAE VAE with first-class functions
  - Concrete and Abstract Syntax
  - Interpreter and Natural Semantics

#### First-Class Citizen

In a programming language, an entity is said to be **first-class citizen** if it is treated as a **value**. In other words, it can be

- 1 assigned to a variable,
- 2 passed as an argument to a function, and
- 3 returned from a function.

For example, an integer is obviously a first-class citizen in Scala:

In Scala, **functions** are also **first-class citizens**, and we call them **first-class functions**.

```
def inc(n: Int): Int = n + 1
// 1. We can assign a function to a variable.
val f: Int => Int = inc
// 2. We can pass a function as an argument to a function.
def twice(f: Int \Rightarrow Int, n: Int): Int = f(f(n))
                                   // inc(inc(3)) = 3 + 1 + 1 = 5
twice(inc, 3)
List(1, 2, 3).map(inc)
                                 // List(2, 3, 4)
// 3. We can return a function from a function.
def addN(n: Int): Int => Int = m => n + m
val add3: Int => Int = addN(3)
                                   //3 + 5 = 8
add3(5)
                                   // 3 + 5 = 8 -- currying
addN(3)(5)
```

### First-Order Functions

### In functional programming, functions are first-class functions.

• Scala

• Python

• Rust

• Haskell

•

#### Contents

1. First-Class Functions

### FVAE – VAE with First-Class Functions Concrete Syntax Abstract Syntax

3. Interpreter and Natural Semantics for F1VAE
Closures – Functions as Values
Addition and Multiplication
Anonymous Functions
Function Application
Function Application (Dynamic Scoping)

Now, we want to extend VAE into FVAE with **first-class functions** rather than **first-order functions** in F1VAE.

```
/* FVAE */
val addN = n => m => n + m;
val add3 = addN(3);
add3(5) // 3 + 5 = 8
```

```
/* FVAE */
val inc = x => x + 1;
val twice = f => n => f(f(n));
twice(inc)(5) // 5 + 1 + 1 = 7
```

- For FVAE, we need to extend **expressions** with
  - 1 anonymous (lambda) functions
  - **2** function applications

### Concrete Syntax

Let's define the concrete syntax of FVAE in BNF:

- For FVAE, we need to extend expressions with
  - 1 anonymous (lambda) functions
  - g function applications

Why not the following function application syntax?

```
| <id> "(" <expr> ")"
```

We cannot support curried function application (e.g., twice(inc)(5)).

# Abstract Syntax

Let's define the **abstract syntax** of FVAE in BNF:

```
Expressions \mathbb{E} \ni e ::= ...

\begin{vmatrix} val & x=e; & e & (Val) \\ & & & & (Id) \\ & & & & \lambda x.e & (Fun) \\ & & & & & (App) \end{vmatrix}
```

```
enum Expr:
...
case Val(name: String, init: Expr, body: Expr)
case Id(name: String)
// anonymous (lambda) functions
case Fun(param: String, body: Expr)
// function applications
case App(fun: Expr, arg: Expr)
```

For example, let's **parse** the following FVAE program:

```
/* FVAE */
val addN = n => m => n + m;
val add3 = addN(3);
add3(5)
```

Then, the following abstract syntax tree (AST) is produced:

```
Val("addN",
   Fun("n",
     Fun("m"),
     Add(Id("n"), Id("m"))
   )
),
Val("add3",
   App(Id("addN"), Const(3)),
   App(Id("add3"), Const(5))
)
)
```

Closures – Functions as Values Addition and Multiplication Anonymous Functions Function Application Function Application (Dynamic Scoping)

### Closures – Functions as Values

Let's evaluate the following FVAE program:

```
/* FVAE */
val addN = n => m => n + m;
val add3 = addN(3);
add3(5) // 3 + 5 = 8
```

How to evaluate the expression addN(3) and add3(5)?

$$[\operatorname{addN} \mapsto ???] \vdash \operatorname{addN}(3) \Rightarrow ??? \\ [\operatorname{add3} \mapsto ???] \vdash \operatorname{add3}(5) \Rightarrow ???$$

Environments map variables to values. What's values of addN and add3?

Functions! Let's define values as either numbers or functions:

Values 
$$\mathbb{V} \ni v ::= n \mid \lambda x.e$$

However, it is **NOT** what exactly we want to do. Why?

### Closures – Functions as Values

```
/* FVAE */
val addN = n => m => n + m;
val add3 = addN(3);
add3(5) // 3 + 5 = 8
```

$$[\operatorname{addN} \mapsto \lambda n.\lambda m.(n+m)] \vdash \operatorname{addN}(3) \Rightarrow \lambda m.(n+m)$$
 
$$[\operatorname{add3} \mapsto \lambda m.(n+m)] \vdash \operatorname{add3}(5) \Rightarrow ???$$

We know that m represents 5, but what about n?

For **static scoping**, we need to remember the environment when the function is defined as values.

Let's define function values as **closures**, a pair of 1) a **function** and 2) its **environment**:

Values 
$$\mathbb{V} \ni \mathbf{v} ::= \mathbf{n} \mid \langle \lambda \mathbf{x}.\mathbf{e}, \sigma \rangle$$

Then, it works!

$$[\operatorname{addN} \mapsto \langle \lambda n. \lambda m. (n+m), \varnothing \rangle] \quad \vdash \operatorname{addN}(3) \Rightarrow \langle \lambda m. (n+m), [n \mapsto 3] \rangle$$

$$[\operatorname{add3} \mapsto \langle \lambda m. (n+m), [n \mapsto 3] \rangle] \vdash \operatorname{add3}(5) \Rightarrow 8$$

#### Closures – Functions as Values

```
// values
enum Value:
   case NumV(n: BigInt)
   case CloV(param: String, body: Expr, env: Env)
```

$$\begin{array}{ccc} \mathsf{Values} & \mathbb{V} \ni \mathsf{v} ::= \mathsf{n} & (\mathtt{NumV}) \\ & & | & \langle \lambda \mathsf{x}.\mathsf{e}, \sigma \rangle & (\mathtt{CloV}) \end{array}$$

For FVAE, a **value** is either 1) a **number** n or a **closure**  $\langle \lambda x.e, \sigma \rangle$ ,

```
// interpreter
def interp(expr: Expr, env: Env): Value = ???
```

$$\sigma \vdash e \Rightarrow v$$

and the interpreter takes an **expression** e with an **environment**  $\sigma$  and returns a **value** v (either a number or a closure):

### Interpreter and Natural Semantics for FVAE

For FVAE, we need to 1) implement the **interpreter**:

```
def interp(expr: Expr, env: Env): Value = ???
```

and 2) define the **natural semantics** with environments:

where

$$\begin{array}{ll} \mathsf{Environments} & \sigma \in \mathbb{X} \xrightarrow{\mathsf{fin}} \mathbb{V} & (\mathsf{Env}) \\ \mathsf{Integers} & n \in \mathbb{Z} & (\mathsf{BigInt}) \\ \mathsf{Identifiers} & x \in \mathbb{X} & (\mathsf{String}) \end{array}$$

### Addition and Multiplication

```
def interp(expr: Expr, env: Env): Value = expr match
  . . .
  case Add(1, r) => interp(1, env) + interp(r, env)
  case Mul(1, r) => interp(1, env) * interp(r, env)
```

$$\sigma \vdash e \Rightarrow v$$

$$\text{Add } \frac{\sigma \vdash e_1 \Rightarrow v_1 \qquad \sigma \vdash e_2 \Rightarrow v_2}{\sigma \vdash e_1 + e_2 \Rightarrow v_1 + v_2} \qquad \text{Mul } \frac{\sigma \vdash e_1 \Rightarrow v_1 \qquad \sigma \vdash e_2 \Rightarrow v_2}{\sigma \vdash e_1 \times e_2 \Rightarrow v_1 \times v_2}$$

Mul 
$$\frac{\sigma \vdash e_1 \Rightarrow v_1 \qquad \sigma \vdash e_2 \Rightarrow v_2}{\sigma \vdash e_1 \times e_2 \Rightarrow v_1 \times v_2}$$

Is it correct?

# Addition and Multiplication

```
def interp(expr: Expr, env: Env): Value = expr match
   ...
   case Add(1, r) => interp(1, env) + interp(r, env)
   case Mul(1, r) => interp(1, env) * interp(r, env)
```

$$\sigma \vdash e \Rightarrow v$$

$$\text{Add } \frac{\sigma \vdash e_1 \Rightarrow \textcolor{red}{v_1} \qquad \sigma \vdash e_2 \Rightarrow \textcolor{red}{v_2}}{\sigma \vdash e_1 + e_2 \Rightarrow \textcolor{red}{v_1} + \textcolor{red}{v_2}}$$

$$\text{Mul } \frac{\sigma \vdash e_1 \Rightarrow \textcolor{red}{\mathbf{v_1}} \qquad \sigma \vdash e_2 \Rightarrow \textcolor{red}{\mathbf{v_2}}}{\sigma \vdash e_1 \times e_2 \Rightarrow \textcolor{red}{\mathbf{v_1}} \times \textcolor{red}{\mathbf{v_2}}}$$

Is it correct? No!

We can only add or multiply **numbers** rather than arbitrary values.

### Addition and Multiplication

```
def interp(expr: Expr, env: Env): Value = expr match
...

case Add(1, r) => (interp(1, env), interp(r, env)) match
    case (NumV(1), NumV(r)) => NumV(1 + r)
    case (1, r) => error(s"invalid operation: ${1.str} + ${r.str}")

case Mul(1, r) => (interp(1, env), interp(r, env)) match
    case (NumV(1), NumV(r)) => NumV(1 * r)
    case (1, r) => error(s"invalid operation: ${1.str} * ${r.str}")
```

Let's refactor the code to avoid duplication using a helper function.

```
def numBOp(name: String)(
 op: (BigInt, BigInt) => BigInt
)(1: Value, r: Value): Value = (1, r) match
  case (NumV(1), NumV(r)) \Rightarrow NumV(op(1, r))
  case (1, r) => error(s"invalid operation: ${1.str} $name ${r.str}")
val numAdd: (Value, Value) => Value = numBOp("+")(_ + _)
val numMul: (Value, Value) => Value = numBOp("*")(_ * _)
def interp(expr: Expr, env: Env): Value = expr match
 case Add(1, r) => numAdd(interp(1, env), interp(r, env))
 case Mul(1, r) => numMul(interp(1, env), interp(r, env))
```

$$\sigma \vdash e \Rightarrow v$$

$$\text{Add } \frac{\sigma \vdash e_1 \Rightarrow \textit{n}_1 \qquad \sigma \vdash e_2 \Rightarrow \textit{n}_2}{\sigma \vdash e_1 + e_2 \Rightarrow \textit{n}_1 + \textit{n}_2} \qquad \text{Mul } \frac{\sigma \vdash e_1 \Rightarrow \textit{n}_1 \qquad \sigma \vdash e_2 \Rightarrow \textit{n}_2}{\sigma \vdash e_1 \times e_2 \Rightarrow \textit{n}_1 \times \textit{n}_2}$$

$$\texttt{Mul} \ \frac{\sigma \vdash e_1 \Rightarrow \textit{\textbf{n}}_1 \qquad \sigma \vdash e_2 \Rightarrow}{\sigma \vdash e_1 \times e_2 \Rightarrow \textit{\textbf{n}}_1 \times \textit{\textbf{n}}_2}$$

# **Anonymous Functions**

```
def interp(expr: Expr, env: Env): Value = expr match
    ...
    case Fun(p, b) => ???
```

$$\sigma \vdash e \Rightarrow v$$

Fun 
$$\frac{1}{\sigma \vdash \lambda x.e \Rightarrow ???}$$

# **Anonymous Functions**

```
def interp(expr: Expr, env: Env): Value = expr match
    ...
    case Fun(p, b) => CloV(p, b, env)
```

$$\sigma \vdash e \Rightarrow v$$

Fun 
$$\sigma \vdash \lambda x.e \Rightarrow \langle \lambda x.e, \sigma \rangle$$

Construct a closure  $\langle \lambda x.e, \sigma \rangle$  from the function  $\lambda x.e$  with the current environment  $\sigma$  for **static scoping**.

```
def interp(expr: Expr, env: Env): Value = expr match
    ...
    case App(f, e) => ???
```

$$\sigma \vdash e \Rightarrow v$$

$$App \frac{???}{\sigma \vdash e_0(e_1) \Rightarrow ???}$$

```
def interp(expr: Expr, env: Env): Value = expr match
   ...
   case App(f, e) => interp(f, env) match
      case CloV(p, b, fenv) => ...
   case v => error(s"not a function: ${v.str}")
```

$$\sigma \vdash e \Rightarrow v$$

App 
$$\frac{\sigma \vdash e_0 \Rightarrow \langle \lambda x. e_2, \sigma' \rangle \qquad \dots}{\sigma \vdash e_0(e_1) \Rightarrow ???}$$

First, evaluate the function expression  $e_0$ , check that it is a closure, and let  $\langle \lambda x. e_2, \sigma' \rangle$  be the closure.

```
def interp(expr: Expr, env: Env): Value = expr match
   ...
   case App(f, e) => interp(f, env) match
      case CloV(p, b, fenv) => ... interp(e, env) ...
   case v => error(s"not a function: ${v.str}")
```

$$\sigma \vdash e \Rightarrow v$$

$$\operatorname{App} \frac{\sigma \vdash e_0 \Rightarrow \langle \lambda x. e_2, \sigma' \rangle \quad \sigma \vdash e_1 \Rightarrow v_1 \quad \dots}{\sigma \vdash e_0(e_1) \Rightarrow ???}$$

Then, evaluate the argument expression  $e_1$  and let  $v_1$  be the resulting value.

```
def interp(expr: Expr, env: Env): Value = expr match
   ...
   case App(f, e) => interp(f, env) match
      case CloV(p, b, fenv) => interp(b, fenv + (p -> interp(e, env)))
      case v => error(s"not a function: ${v.str}")
```

$$\sigma \vdash e \Rightarrow v$$

$$\operatorname{App} \frac{\sigma \vdash e_0 \Rightarrow \langle \lambda x. e_2, \overline{\sigma'} \rangle \qquad \sigma \vdash e_1 \Rightarrow v_1 \qquad \overline{\sigma'}[x \mapsto v_1] \vdash e_2 \Rightarrow v_2}{\sigma \vdash e_0(e_1) \Rightarrow v_2}$$

Finally, evaluate the body expression  $e_2$  in the environment  $\sigma'[x \mapsto v_1]$ , where  $\sigma'$  denotes the environment captured at the **definition** site of the function for **static scoping**.

# Function Application (Dynamic Scoping)

```
def interp(expr: Expr, env: Env): Value = expr match
   ...
   case App(f, e) => interp(f, env) match
   case CloV(p, b, fenv) => interp(b, env + (p -> interp(e, env)))
   case v => error(s"not a function: ${v.str}")
```

$$\sigma \vdash e \Rightarrow v$$

$$\operatorname{App} \frac{\sigma \vdash e_0 \Rightarrow \langle \lambda x. e_2, \sigma' \rangle \qquad \sigma \vdash e_1 \Rightarrow v_1 \qquad \sigma[x \mapsto v_1] \vdash e_2 \Rightarrow v_2}{\sigma \vdash e_0(e_1) \Rightarrow v_2}$$

We can define **dynamic scoping** by using the current environment  $\sigma$  instead of the environment  $\sigma'$  captured at the definition site of the function.

# Function Application (Dynamic Scoping)

```
/* FVAE (static scoping) */
val x = 3;
val f = y => x * y;
val x = 4;
f(5) // 3 * 5 = 15
```

where

$$\begin{array}{rcl}
\sigma_0 & = & [x \mapsto 3] \\
\sigma_1 & = & [x \mapsto 4, f \mapsto \langle \lambda y.(x \times y), \sigma_0 \rangle]
\end{array}$$

### Summary

### Exercise #4

- Please see this document<sup>1</sup> on GitHub.
  - Implement interp function.
  - Implement interpDS function.
- It is just an exercise, and you don't need to submit anything.
- However, some exam questions might be related to this exercise.

<sup>1</sup>https://github.com/ku-plrg-classroom/docs/tree/main/cose212/fvae.
